

Symbolic dynamics and relatively hyperbolic groups

François Dahmani*, Ashi Yaman†

Abstract : We study the action of a relatively hyperbolic group on its boundary, by methods of symbolic dynamics. Under a condition on the parabolic subgroups, we show that this dynamical system is finitely presented. We give examples where this condition is satisfied, including geometrically finite kleinian groups.

Associated to any word-hyperbolic group Γ , there is a dynamical system arising from the action of Γ on its Gromov boundary $\partial\Gamma$. Already in [12], M.Gromov uses methods of symbolic dynamics for the study of this action, and in [5] (see also [6]), M.Coornaert, and A.Papadopoulos explain a way to factorize such a dynamical system through a subshift of finite type. They describe a finite alphabet $\mathcal{A}$, and a subshift $\Phi \subset \mathcal{A}^\Gamma$, and they construct a continuous equivariant, surjective map $\Phi \rightarrow \partial\Gamma$, which encodes the action of Γ on its boundary by a subshift of finite type.

The action of a group Γ on a compact metric space, K is expansive if there exists $\varepsilon > 0$ such that any pair of distinct points in K can be taken at distance at least ε from each other by an element of Γ . It is well known that the action of a hyperbolic group Γ on $\partial\Gamma$ is expansive. This property, together with the existence of the coding given in [5], makes the action of a hyperbolic group, Γ , on its boundary, $\partial\Gamma$, *finitely presented* (see [12], [5]). In [12], M.Gromov describes consequences of such a presentation, like the rationality of some counting functions.

The aim of this paper is to state and prove similar properties for relatively hyperbolic groups, where parabolic subgroups are allowed. In general, in presence of parabolics, the study of dynamical properties becomes significantly more complicated.

After an idea of Gromov in [12], B.Farb [10] and B.Bowditch [2] developed the theory of relatively hyperbolic groups, as a generalization of geometrically finite Kleinian groups. We will use for this work the definition of relatively hyperbolic groups given by Bowditch in [2]. A group Γ is hyperbolic relative to a family, $\mathcal{G}$, of finitely generated subgroups of Γ if it acts on an hyperbolic fine graph, with finite stabilizers of edges, finitely many orbits of edges, and such that the stabilizers of infinite valence vertices are exactly the elements of $\mathcal{G}$ (see Definition 2.3). In [10], this definition is equivalent to “relatively hyperbolic with the property BCP” (see the appendix of [9]).

If one replaces “fine” by “locally finite” in above definition, then $\mathcal{G}$ is empty and the group is hyperbolic. In [10], Farb proves that the fundamental group of a finite volume manifold of pinched negative curvature, with finitely many cusps is hyperbolic relative to the conjugates of the fundamental groups of the cusps, which are virtually nilpotent. Sela’s limit groups, or, finitely generated ω -residually-free groups are hyperbolic relative to their maximal abelian non-cyclic subgroups, as shown in [8].

Bowditch describes a boundary for a relatively hyperbolic group in [2]. The group acts on this compact set as a convergence group, and the elements of the family $\mathcal{G}$ are parabolic subgroups for this action. Despite of those parabolic subgroups, the action is expansive (Proposition 3.18).

†University of Southampton, e-mail : a.yaman@maths.soton.ac.uk

Although the construction of the subshift of finite type given by Coornaert and Papadopoulos will not work properly here (either one would need an infinite alphabet, or the map $\Phi \rightarrow \partial\Gamma$ would not be well defined) we found an intrinsic property of the maximal parabolic subgroups that allows successful modifications.

An infinite group has its one-point compactification $G \cup \{\infty\}$ finitely presented with special symbol if there exists an alphabet $\mathcal{A}$, a subshift of finite type $\Phi \subset \mathcal{A}^G$, a continuous surjective G -invariant map $\Pi : \Phi \rightarrow (G \cup \{\infty\})$, and a special symbol $\$ \in \mathcal{A}$, such that, for $\sigma \in \Phi$, $\Pi(\sigma) = g \in G$ if and only if $\sigma(g) = \$$. One can reformulate this definition including finite groups by considering their Alexandrof compactifications. If the action of a discrete group on its Alexandrof compactification is finitely presented with special symbol then we say that the group has *the property of special symbol*.

Theorem 0.1 *Let $(\Gamma, \mathcal{G})$ be a relatively hyperbolic group, and $\partial\Gamma$ be its boundary (in the sense of Bowditch [2]).*

If each $G \in \mathcal{G}$ has the property of special symbol, then the action of Γ on its boundary $\partial\Gamma$ is finitely presented.

One should remark that in [5] the subshift coding the action of hyperbolic groups to its boundary enables algorithmic computations. Here in order to simplify the proof we give a weak version of the result for relatively hyperbolic groups. However we refer to the thesis of second author ([14]) for a complete proof of the above theorem which enables computations.

We see that there is the natural question arising from above result.

Problem. *Which groups have the property of special symbol?*

The following results answer partially this question and give some examples. However we do not have a complete list of groups satisfying the special symbol property.

Theorem 0.2 *If a group has the property of special symbol, then it is finitely generated.*

A group Γ is said to be *poly-hyperbolic* if there is a sequence of subgroups $\{1\} = N_0 \triangleleft N_1 \triangleleft \dots \triangleleft N_{k-1} \triangleleft N_k = \Gamma$, with all the quotients N_{i+1}/N_i hyperbolic.

Theorem 0.3 *Poly-hyperbolic groups have the property of special symbol. In particular, this includes poly-cyclic groups.*

Corollary 0.4 *A geometrically finite group [4] of isometries of a simply connected manifold of pinched negative curvature acts as a finitely presented system on its limit set.*

We give in section 1 definitions related to symbolic dynamics. In section 2 we define relatively hyperbolic groups, their boundaries and introduce some tools such as "angles" and "cones". We prove the Theorem 0.1 in Section 3. The subshift we construct will produce objects which are local Busemann functions on the fine hyperbolic graph associated to the relatively hyperbolic group. To associate a point in the boundary to an element of the subshift, we consider its gradient lines. We prove that they converge to points at infinity, and we make sure that, for a given element of the subshift, all the gradient lines converge to the same point. For this we use the property of special symbol for each stabilizer of infinite valence vertex. In Section 4 we study this property of special symbol, and in particular, prove Theorem 0.2.

We want to thank B.Bowditch, and T.Delzant, for their many comments, and M.Coornaert for his useful explanations. We also thank the referee, for his/her useful comments.

1 Definitions, symbolic dynamics

We borrow the following definitions (1.1 to 1.4) from Gromov [12] 8.4, and Coornaert and Papadopoulos [5], chapter 2. See also Fried [11].

Definition 1.1 (*Shift, subshift, subshift of finite type*) ([12], 8.4, [5], Chap. 2)

If $\mathcal{A}$ is a finite discrete alphabet and Γ is a group, $\mathcal{A}^\Gamma$, with the product topology, is the total shift of Γ on $\mathcal{A}$. It admits a natural left Γ -action given by $(\gamma\sigma)(g) = \sigma(\gamma^{-1}g)$ for all $g \in \Gamma$, $\sigma \in \mathcal{A}^\Gamma$.

A closed Γ -invariant subset of $\mathcal{A}^\Gamma$ is called a subshift.

A cylinder $\mathcal{C}$ is a subset of the total shift such that there exists a finite set $F \subset \Gamma$, and a family of maps $M \subset \mathcal{A}^F$ with

$$\mathcal{C} = \{\sigma \in \mathcal{A}^\Gamma \mid \sigma|_F \in M\}.$$

Φ is a subshift of finite type if there exists a cylinder $\mathcal{C}$ such that $\Phi = \bigcap_{\gamma \in \Gamma} \gamma^{-1}\mathcal{C}$.

The subshifts of finite type are subshifts, but the cylinders are not Γ -invariant.

Definition 1.2 (*Dynamical systems of finite type*) [12], [5]

Let Γ act on a compact set K . The dynamical system is of finite type if there exists a finite alphabet $\mathcal{A}$, a subshift of finite type $\Phi \subset \mathcal{A}^\Gamma$ and a continuous, surjective, Γ -equivariant map $\pi : \Phi \rightarrow K$.

Example : Set $\Gamma = \mathbb{Z}$, and $\mathcal{A} = \{a, b, \$\}$. The cylinder $\mathcal{C}$ is the set of the maps that agree on $F = \{0, 1\}$ with one of the maps in $M = \{m_i, i = 1 \dots 4\}$ where $(m_1 : 0, 1 \rightarrow a, a)$, $(m_2 : 0, 1 \rightarrow a, \$)$, $(m_3 : 0, 1 \rightarrow \$, b)$ and $(m_4 : 0, 1 \rightarrow b, b)$.

Let Φ be the subshift of finite type defined by the cylinder $\mathcal{C}$, i.e $\Phi = \bigcap_{n \in \mathbb{Z}} n + \mathcal{C}$, where $n + \mathcal{C}$ is the translate of the cylinder $\mathcal{C}$ of the total shift $\mathcal{A}^\mathbb{Z}$, by the element n of $\mathbb{Z}$. One can check that the elements of Φ are the constant word on a , the constant word on b and all the words $(\dots aaa\$bbb\dots)$ beginning by a , until there is a $\$$ on the n^{th} letter ($n \in \mathbb{Z}$) and then b . Although for this example Φ is countable, in general subshifts of finite type are not countable.

Now consider the compact set $K = \mathbb{Z} \cup \{\infty\}$ with the usual topology. There is a natural left action of $\mathbb{Z}$ on K , fixing the infinity point. Consider the map $\pi : \Phi \rightarrow K$ that sends $(\dots aaaa\dots)$ and $(\dots bbbb\dots)$ on ∞ , and $(\dots aaa\$bbb\dots)$ on $n \in \mathbb{Z}$ where n is the index of the letter $\$$. The map π is surjective, continuous and equivariant, and therefore the action of $\mathbb{Z}$ on K is of finite type.

We now continue with definitions. One can refine the property of being a dynamical system of finite type with the following.

Definition 1.3 (*Expansivity*)

The action of a group Γ on a compact set K is expansive if there exists U a neighbourhood of the diagonal $\Delta \subset K \times K$ such that $\Delta = \bigcap_{\gamma \in \Gamma} \gamma U$.

Note that, if the compact set is metric, this is equivalent to the definition of expansivity given in introduction (see [5], Proposition 2.3).

Definition 1.4 (*Finitely presented dynamical systems*)[12], [5]

Let Γ act on a compact K . The dynamical system is finitely presented if it is both of finite type and expansive.

If one has a subshift of finite type $\Phi \subset \mathcal{A}^\Gamma$ and a surjective continuous equivariant map $\pi : \Phi \rightarrow K$, the expansivity of the action of Γ on K turns out to be equivalent to the fact that the subshift $\Psi \subset (\mathcal{A} \times \mathcal{A})^\Gamma$ defined by $[(\sigma_1 \times \sigma_2) \in \Psi] \Leftrightarrow [\pi(\sigma_1) = \pi(\sigma_2)]$, is of finite type (cf [5] chapter 2).

If Γ is a infinite discrete group, it acts on its one-point compactification $\Gamma \cup \{\infty\}$ by multiplication of the left, hence fixing the point at infinity. This one-point compactification is also the Alexandrov compactification of Γ , but if Γ is finite, its Alexandrov compactification is itself.

Definition 1.5 (*The property of special symbol*)

A discrete group Γ is has the property of special symbol if the Γ -action on the Alexandrov compactification, $\Gamma \cup \{\infty\}$ (or respectively on Γ if Γ is finite), is finitely presented by a subshift $\Phi \subset \mathcal{A}^\Gamma$ and if the presentation map $\pi : \Phi \rightarrow \Gamma \cup \{\infty\}$ (resp. $\pi : \Phi \rightarrow \Gamma$) satisfies

$$\exists \$ \in \mathcal{A} \quad (\pi(\sigma) = \gamma \in \Gamma) \Leftrightarrow (\sigma(\gamma) = \$)$$

Note that in this case, the property of expansivity of Γ , on $K = \Gamma \cup \{\infty\}$ is always satisfied (consider $U = (\Gamma \times \Gamma) \cup (\{\infty\} \times (K \setminus \{1_\Gamma\})) \cup ((K \setminus \{1_\Gamma\}) \times \{\infty\})$ in the definition 1.3). The example of dynamical system of finite type described previously has the property of special symbol of $\mathbb{Z}$. Note also that all finite groups have trivially the property of special symbol.

We give in section 4 several examples of groups which has the property of special symbol.

2 About Relatively Hyperbolic Groups

2.1 Definitions

A *graph* is a set of *vertices* with a set of *edges*, where an edge is an unordered pair of vertices. One can equip the geometrical realization of a graph with a metric where edges have length 1. Thus this geometrical realization allows to consider simplicial, geodesic, quasi-geodesic and locally geodesic paths in a graph. (see for example [1])

Definition 2.1 (*Circuits*)

A circuit in a graph is a simple simplicial loop, i.e without self intersection.

In [2], B. Bowditch introduces the notion of fineness of a graph.

Definition 2.2 (*Fineness*)[2]

A graph $\mathcal{K}$ is fine if for every $L > 0$, and for every edge e , the set of the circuits of length less than L , containing e is finite. It is uniformly fine if this set has cardinality bounded above by a constant depending only on L .

Definition 2.3 (*Relatively Hyperbolic Groups*)[2]

A group Γ is hyperbolic relative to a family of subgroups $\mathcal{G}$, if it acts on a Gromov-hyperbolic, fine graph $\mathcal{K}$, such that stabilizers of edges are finite, such that there are finitely many orbits of edges, and such that the stabilizers of the vertices of infinite valence are finitely generated and they are exactly the elements of $\mathcal{G}$.

With an abuse of language, we will say that the pair $(\Gamma, \mathcal{G})$ is a relatively hyperbolic group, and that $\mathcal{K}$ is a graph associated to it.

We note that as there are finitely many orbits of edges, a graph associated to a relatively hyperbolic group is uniformly fine. Note also that the graph $\mathcal{K}$ associated to $(\Gamma, \mathcal{G})$, can be chosen to be without global cut point, and with positive hyperbolicity constant δ . This will ensure that all the angles (introduced in the following arguments) are finite.

2.2 Angles

For any graph, one can define a notion of *angle* as follow.

Definition 2.4 (*Angles*)

Let $\mathcal{K}$ be a graph, and let $e_1 = (v, v_1)$ and $e_2 = (v, v_2)$ be edges with one common vertex v . The angle $\text{Ang}_v(e_1, e_2)$, is the length of the shortest path from v_1 to v_2 , in $\mathcal{K} \setminus \{v\}$ ($+\infty$ if there is none).

The angle $\text{Ang}_v(p, p')$ between two simple simplicial (oriented) paths p and p' , starting from a common vertex v , is the angle between their first edges after this vertex.

If p is a simple simplicial path, and v one of its vertices, $\text{Ang}_v(p)$ is the angle between the consecutive edges of p at v , and its maximal angle $\text{MaxAng}(p)$ is the maximal angle between consecutive edges of p .

In the notation $\text{Ang}_v(p, p')$, we will sometimes omit the subscript if there is no ambiguity.

Proposition 2.5 (*Some useful remarks*)

1. $\text{Ang}_v(e_1, e_3) \leq \text{Ang}_v(e_1, e_2) + \text{Ang}_v(e_2, e_3)$ when e_i are edges incident on a vertex v .
2. If γ is an isometry of $\mathcal{K}$, $\text{Ang}_v(e_1, e_2) = \text{Ang}_{\gamma v}(\gamma \cdot e_1, \gamma \cdot e_2)$.
3. Any circuit of length $L \geq 2$ has a maximal angle less than $L - 2$.

Proof. The first remark is the triangular inequality for the length distance of $\mathcal{K} \setminus \{v\}$. The second statement is obvious. Finally, if $e_1 = (v_1, v)$ and $e_2 = (v, v_2)$ are two consecutive edges in the circuit, the circuit itself gives a path of length $L - 2$ from v_1 and v_2 avoiding v . $\square$

Here is an important property of angles.

Lemma 2.6 (*Large angles in triangles*)

Let $[x, y]$ and $[x, z]$ be geodesic segments in a δ -hyperbolic graph, and assume that $\text{Ang}_x([x, y], [x, z]) = \theta \geq 50\delta$. Then the concatenation of the two segments is still a geodesic. Moreover any geodesic segment $[y, z]$ will contain x and $\text{Ang}_x([y, z]) \geq \theta - 50\delta$.

Proof. Let $[y, z]$ be a geodesic, defining a triangle (x, y, z) , which is δ -thin, that is : any segment $[y, z]$ is in the δ -neighbourhood of the set $[x, y] \cup [x, z]$. We consider the vertices y' and z' on $[x, y]$ and $[x, z]$ located at distance 10δ from x . They are not 3δ -close to each other. Indeed, if they were, there would be a loop of length less than 23δ containing x and the firsts edges of $[x, y]$ and $[x, z]$, and not returning to x , which contradicts the fact that the angle of these path at x is more than 50δ . Therefore, they are δ -close to the segment $[y, z]$, and we set y'' and z'' the corresponding points on $[y, z]$. This gives a loop of length less than $(2 \times 10\delta + 2\delta) \times 2 \leq 50\delta$, containing x , consisting of $[x, y']$, $[y', y'']$, $[y'', z'']$, $[z'', z']$, and $[z', x]$. As the small segments $[y', y'']$ and $[z'', z']$ are 10δ far away from x , they do not contain x . Thus the third property of Proposition 2.5 proves that $x \in [y'', z'']$, and $\text{Ang}_x([y'', z'']) \geq \theta - 50\delta$, and therefore $\text{Ang}_x([y, z]) \geq \theta - 50\delta$. $\square$

2.3 Cones

Definition 2.7 (*Cones*)

Let $\mathcal{K}$ be a graph, let d and θ be positive numbers. The cone centred at an edge $e = (v, v')$, of radius d and angle θ is the set of vertices w at distance at most d from v and such that there exists a geodesic segment $[v, w]$ the maximal angle and the angle with e of which are less than θ , i.e. :

$$\text{Cone}_{d,\theta}(e, v) = \{w \in \mathcal{K} \mid \text{dist}(w, v) \leq d, \text{MaxAng}[v, w] \leq \theta, \text{Ang}_v(e, [v, w]) \leq \theta\}$$

Proposition 2.8 (*Bounded angles imply local finiteness*)

Let $\mathcal{K}$ be a fine graph. Given an edge e and $\theta > 0$, there exists only finitely many edges e' such that e and e' have a common vertex, and $\text{Ang}(e, e') \leq \theta$.

Proof. Only finitely many circuits shorter than θ contain e . $\square$

Corollary 2.9 (*Cones are finite*)

In a fine graph, the cones are finite sets of vertices. If the graph is uniformly fine, the cardinality of $\text{Cone}_{d,\theta}(e, v)$ can be bounded above by a function of d and θ .

Proof. Consider a cone $\text{Cone}_{d,\theta}(e, v)$. We argue by induction on d . If $d = 1$, the result is given by the previous proposition. If $d > 1$, we remark that $\text{Cone}_{d,\theta}(e, v)$ is contained in the union of cones of angle θ and radius 1, centered at edges whose vertices are both in $\text{Cone}_{(d-1),\theta}(e, v)$. If the latter is finite, the union is also finite. $\square$

Here is a visibility property for hyperbolic fine graphs. It is an usual result for proper hyperbolic graphs.

Proposition 2.10 (*Visibility property in fine hyperbolic graphs*)

Let $\mathcal{K}$ a hyperbolic fine graph, and $\partial\mathcal{K}$ its Gromov boundary. Then for all $\xi \in \partial\mathcal{K}$, and for all vertex v in $\mathcal{K}$, there exists a geodesic ray $\rho = [v, \xi)$ in $\mathcal{K}$.

For all ξ and ξ' in $\partial\mathcal{K}$, there exists a bi-geodesic ray $\rho' = (\xi, \xi')$ in $\mathcal{K}$.

Proof. Let us prove the first assertion. Let (v_n) be a sequence of vertices converging to ξ in the sense of the Gromov topology. Consider two segments $[v, v_n]$, and $[v, v_m]$. If their angle at the vertex v is greater than 50δ , we can apply Lemma 2.6 to deduce that the gromov product $(v_n \cdot v_m)_v$ is equal to zero. Therefore, there exists n_0 such that for all $n \geq n_0$, $\text{Ang}_v([v, v_n], [v, v_{n_0}]) \leq 50\delta$. Therefore, the first edges of these segments are all in a cone, and as the graph is fine, it is a finite set. After extraction of a subsequence, we can assume that these edges are all equal. The diagonal extraction process gives a subsequence $(v_{\sigma(n)})_n$ such that $[v, v_{\sigma(n)}]$ coincide with $[v, v_{\sigma(m)}]$ for all $m \geq n$, on a subsegment s_n of length n . As s_n is a subsegment of s_m for all $m \geq n$, their union is a geodesic ray $[v, \xi)$.

For the second assertion, we choose two rays $[v, \xi)$ and $[v, \xi')$. Let $(v_n)_n$ be a sequence of vertices that converges to ξ , on $[v, \xi)$ and $(v'_n)_n$ another sequence that converges to ξ' on $[v, \xi')$. Let $d = (\xi \cdot \xi')_v + 100\delta$, and let r and r' the subsegments of the rays $[v, \xi)$ and $[v, \xi')$, of length d . For all n and m sufficiently large, the geodesic segments $[v_n, v_m]$ intersect the cone of radius d and of angle $\text{MaxAng}(r) + \text{MaxAng}(r') + \text{Ang}_v(r, r') + 100\delta$ centered at the first edge of r .

Therefore, as the cone is finite, one can find a subsequence of v_n and v'_n and a point p in the cone, such that every segment $[v_n, v'_m]$ contains p . Now the diagonal process of the proof of the first assertion gives a sequence of segment converging to a bi-geodesic. $\square$

We will use the following theorem, which is a reformulation of a result in [7].

Theorem 2.11 *Let Γ be a relatively hyperbolic group and $\mathcal{K}$ be an associated graph, which is δ -hyperbolic. There exists an aspherical (in particular simply connected) simplicial complex such that its vertex set is the one of $\mathcal{K}$, and such that each simplex has all its vertices in a same cone of $\mathcal{K}$, of radius $10\delta + 10$, and angle $100\delta + 30$.*

Proof. In [7], the first author defines the *relative Rips complex* $P_{d,r}(\mathcal{K})$ for a relatively hyperbolic group. It is the maximal complex on the set of vertices of $\mathcal{K}$ such that an edge is between two vertices if, in $\mathcal{K}$, a geodesic of length less than d and maximal angle less than r links them.

Although in [7], the notion of angle is replaced by “length of traveling in cosets”, the proof of Theorem 6.2 remains the same, and gives the asphericity of $P_{d,r}(\mathcal{K})$ for large d and r . Theorem 2.11 follows. $\square$

2.4 Boundary of a relatively hyperbolic group

Let $(\Gamma, \mathcal{G})$ be a relatively hyperbolic group, and let $\mathcal{K}$ be an associated graph. In [2], Bowditch defines the (dynamical) boundary $\partial\Gamma$ of Γ by $\partial\Gamma = \partial\mathcal{K} \cup \mathcal{V}_\infty$ where $\partial\mathcal{K}$ is the Gromov boundary of the hyperbolic graph $\mathcal{K}$, and $\mathcal{V}_\infty$ is the set of vertices of infinite valence in $\mathcal{K}$. This boundary admits a natural topology of metrisable compact set (see [2], [3], [13]). Let us recall a convergence criterion for this topology. Let $(v_n)_n$ be a sequence of vertices of infinite valence. If there is a point ξ in $\partial\mathcal{K}$ such that the sequence of Gromov products $(v_n \cdot \xi)_{v_0}$ tends to infinity, then $(v_n)_n$ converges to ξ for the topology of $\partial\Gamma$. If there is a vertex v' in $\mathcal{K}$ such that every geodesic segments $[v_0, v_n]$ contains v' and contains an edge $e_n = (v', v'_n)$ such that all the vertices v'_n , $n \in \mathbb{N}$ are distinct, then the sequence $(v_n)_n$ converges to v' in the topology of $\partial\Gamma$. For a sequence $(\xi_n)_n$ of points in $\partial\mathcal{K}$, the conditions are similar : one needs only to change the segments $[v_0, v_n]$ into geodesic rays $[v_0, \xi_n]$.

3 Finite presentation of the boundaries of a relatively hyperbolic group.

We will prove the following theorem.

Theorem 3.1 *Let $(\Gamma, \mathcal{G})$ be a relatively hyperbolic group. If, for each $G \in \mathcal{G}$, the action of G on its Alexandrov one-point compactification $G \cup \{\infty\}$ has the property of special symbol, then the action of Γ on its boundary $\partial\Gamma$ is finitely presented.*

Let $(G_i)_{i=1..m}$ be a finite family of representatives of conjugacy classes of parabolic subgroups in Γ , each stabilizing an infinite valence vertex p_i in some hyperbolic fine graph $\mathcal{K}$. We also choose, for each $i \leq m$, an arbitrary edge e_i in $\mathcal{K}$, adjacent to p_i . We assume that each G_i acts on $G_i \cup \{\infty\}$ as a finitely presented system with a special symbol. That means that we have an alphabet $\mathcal{A}_i$, a finite subset $F_i \subset G_i$ and a set M_i of maps from F_i to $\mathcal{A}_i$ which define a cylinder, hence a subshift of finite type Φ_i . We will denote by $\$$ the special symbol in $\mathcal{A}_i$, without distinguishing the indices i .

Without loss of generality, we can choose that the graph $\mathcal{K}$ is such that for all i , and for all $\gamma \in F_i$, $\text{Ang}(e_i, \gamma e_i) \leq 1$. We choose also $\mathcal{K}$ to be without cut point (all the angles are finite).

3.1 Busemann and radial cocycles

Definition 3.2 (Busemann function)(see [12] 7.5.C, and [5] chap. 3, section 3)

Let $\rho : [0, \infty) \rightarrow \mathcal{K}$ be a geodesic ray starting at v_0 . The Busemann function $h_\rho : \mathcal{V} \rightarrow \mathbb{Z}$ of ρ is defined by the limit (which always exists and is finite) $h_\rho(v) = \lim_{n \rightarrow \infty} (\text{dist}(v, \rho(n)) - n)$.

Definition 3.3 (Busemann cocycles)([12] 7.5.E, [5] chap. 3)

Let h_ρ be a Busemann function. The cocycle associated to h_ρ is $\varphi_\rho : \mathcal{V} \times \mathcal{V} \rightarrow \mathbb{Z}$ defined by $\varphi_\rho(w, v) = h_\rho(v) - h_\rho(w)$. A gradient line of φ_ρ is a sequence of vertices $(v_n)_n$ such that $\varphi_\rho(v_{i+1}, v_i) = 1$ for all i .

The proof of the next lemma can be found in [5] (Proposition 4.2), for locally finite graphs, which is not the case here. But in fact, the proof given depends only a visibility property of the boundary, which is satisfied here (Proposition 2.10).

Lemma 3.4 *If φ is a Busemann cocycle associated to ρ , then a gradient line is a sequence of vertices of a geodesic ray asymptotic to ρ . Moreover there is a gradient line starting from each vertex.*

Definition 3.5 *(Radial cocycles)*

Let p be a vertex of infinite valence in $\mathcal{K}$. The radial cocycle associated to p is $\varphi_p : \mathcal{V} \times \mathcal{V} \rightarrow \mathbb{Z}$ defined by $\varphi_p(w, v) = \text{dist}(v, p) - \text{dist}(w, p)$. A gradient line of φ_p is a finite family of vertices $(v_n)_{0 \leq n \leq m}$ such that $\varphi_p(v_{i+1}, v_i) = 1$ for all i , and $v_m = p$.

The next lemma is direct by definition.

Lemma 3.6 *If φ is a radial cocycle associated to p , then its different gradient lines are exactly the sequences of vertices of geodesic segments ending at p .*

Let δ be a positive hyperbolicity constant of $\mathcal{K}$. We set $\theta \geq 2000\delta$ and such that for every vertex of finite valence in $\mathcal{K}$, for every pair of edges adjacent to this vertex, their angle is at most θ .

Proposition 3.7 *(Properties of Busemann and radial cocycles)*

Let φ be a Busemann or a radial cocycle. Then :

1. (Integral values) For x, y adjacent vertices, $\varphi(x, y)$ is 0, 1 or -1 .
2. (Cocycle) For all x, y, z $\varphi(x, y) + \varphi(y, z) + \varphi(z, x) = 0$.
3. (Geodesic extension) Let ξ be a point of $\partial\Gamma$ (i.e. a point of $\partial\mathcal{K}$ or a vertex of infinite valence of $\mathcal{K}$), and let $l = [v, \xi)$ be a gradient line and $[x, v]$ a geodesic segment (of length and maximal angle less than θ), such that $\text{Ang}_v([x, v] \cup [v, \xi)) \geq \theta$, then $[x, v] \cup [v, \xi)$ is a gradient line.
4. (Exits) If v is a vertex of finite valence, then there exists w adjacent to v with $\varphi(w, v) = 1$.

Proof. Properties 1 and 2 are obvious. Property 4 is consequence of the Lemmas 3.4 and 3.6. Property 3 deserves a proof here. We precise that the assumption of maximal angle for the segment $[x, v]$ is unnecessary here, but will be useful elsewhere in this paper, where we prove that some other objects satisfy the same properties (see 3.11). By Lemma 3.4 (if $\xi \in \partial\mathcal{K}$) and Lemma 3.6 (if ξ is a vertex of infinite valence), any gradient line from x is a geodesic ray $[x, \xi)$ and produces a triangle (x, v, ξ) , which, by assumption, has a large angle at v . Hence, by Lemma 2.6, any ray $[x, \xi)$ contains v . $\square$

3.2 Shift and subshift

For all $i = 1 \dots m$ we set $F'_i = \{\gamma \in G_i \mid \text{Ang}_{p_i}(e_i, \gamma e_i) \leq \theta/2\}$. This set contains F_i .

We fix a vertex v_0 and an edge $e_0 = (v_0, v)$. We choose R and Θ sufficiently large, such that for all $i = 1 \dots m$, $\text{Cone}_{10\theta, 10\theta}(e_i, p_i) \subset \text{Cone}_{R, \Theta}(e_0, v_0)$. Note that $\theta \geq 2000\delta$, hence R and Θ are greater than $(100\delta + 30)$, the constant given by Theorem 2.11.

Let $\mathcal{A}'$ denote the set of all possible restrictions of Busemann and radial cocycles on $\text{Cone}_{R, \Theta}(e_0, v_0) \times \text{Cone}_{R, \Theta}(e_0, v_0)$. We set $\mathcal{A}'' = \mathcal{A}_1 \times \dots \times \mathcal{A}_m$. We choose our alphabet to be $\mathcal{A} = \mathcal{A}' \times \mathcal{A}''$

Lemma 3.8 $\mathcal{A} = \mathcal{A}' \times \mathcal{A}''$ is finite.

Proof. Cones are finite, and cocycles have integral values bounded by the diameter. $\square$

An element ψ of $\mathcal{A}^\Gamma$ is a map from Γ to $\mathcal{A} = \mathcal{A}' \times \mathcal{A}''$. Thus it has coordinates $\psi_0 : \Gamma \rightarrow \mathcal{A}'$ and $\psi_i : \Gamma \rightarrow \mathcal{A}_i$ for all i . Hence, $\psi_0(\gamma)$ is a map from $\text{Cone}_{R,\Theta}(e_0, v_0) \times \text{Cone}_{R,\Theta}(e_0, v_0)$ to $\mathbb{Z}$, whereas $\psi_i(\gamma)$ is in $\mathcal{A}_i$ for $i \geq 1$.

Let F be the set of elements in Γ such that the vertices of $\gamma.e_0$ are both in $\text{Cone}_{R,\Theta}(e_0, v_0)$. As stabilizers of edges are finite, F is a finite set.

Let $\mathcal{C}$ be the cylinder (in the sense of Definition 1.1) defined on F so that $\psi \in \mathcal{C}$ if the three next conditions, which concern only finitely many elements of Γ , are fulfilled :

- $[\psi_0(\gamma)](v_1, v_2) = [\psi_0(1_\Gamma)](\gamma^{-1}v_1, \gamma^{-1}v_2)$ whenever $v_1, v_2, \gamma^{-1}v_1, \gamma^{-1}v_2$ are all in $\text{Cone}_{R,\Theta}(e_0, v_0)$.
- $\psi_i|_{F_i}$ is in M_i .
- for $\gamma \in F_i$, for v such that $\gamma.e_i = (p_i, v)$, and for w such that $[w, p_i]$ is a geodesic segment of length, and maximal angle, less than θ , containing v , one has $[\psi_0(\gamma)](\gamma^{-1}w, p_i) \geq (1 - \text{dist}(w, p_i))$ only if there exists $\gamma' \in F'_i$ such that $\psi_i(\gamma\gamma') = \$$.

Denote by Φ the subshift of finite type $\Phi = \bigcap_{\gamma \in \Gamma} \gamma\mathcal{C}$.

We will see in the next lemmas that the second point of the subshift allows us to say that at a vertex of infinite valence there is at most one edge issued from this vertex for which the i th coordinate of ψ takes the symbol $\$$. Moreover the third point of the subshift will ensure that the gradient lines escape a vertex of infinite valence only around the edge which takes the symbol $\$$.

Lemma 3.9 (*Globalisation*)

Let $\psi \in \Phi$. If v and v' are vertices in $\gamma\text{Cone}_{R,\Theta}(e_0, v_0)$, we set $\varphi_\psi(v, v') = \psi_0(\gamma)(\gamma^{-1}v, \gamma^{-1}v')$. Then the map φ_ψ is well defined. Moreover φ_ψ can be extend to all pair of vertices of $\mathcal{K}$.

Proof. Because of the first property of the definition of $\mathcal{C}$, the formula given for $\varphi_\psi(v, v')$ does not depend on the choice of possible γ , and therefore, the map is well defined. Now, the map φ_ψ is defined on pairs of vertices lying in a same translate of $\text{Cone}_{R,\Theta}(e_0, v_0)$ and takes integral values, (first property of Proposition 3.7) on the translate of this cone as it is a restriction of a busemann or a radial cocycle by definition of our alphabet. Thus it can be seen as a 1-cochain defined on the relative Rips complex given by Theorem 2.11, which is simply connected. As it is a cocycle, it is a coboundary, and there is a map $\tilde{\varphi}$ defined on the set of vertices of $\mathcal{K}$ such that $\varphi_\psi(w, v) = \tilde{\varphi}(w) - \tilde{\varphi}(v)$ for all v, w lying in a translate of $\text{Cone}_{R,\Theta}(e_0, v_0)$. This formula allows to extend the cocycle φ_ψ to all pair of vertices (not only those in a same cone of radius R and angle Θ). $\square$

From now on we will assume that φ_ψ is defined globally.

Lemma 3.10 (*About the ψ_i , $i \geq 1$*)

Let $\psi \in \Phi$, and $\gamma \in \Gamma$, for all i , $\psi_i|_{\gamma.G_i}$ is an element of Φ_i .

Proof. By definition of $\mathcal{C}$, for all γ , and all $g_i \in G_i$, $\psi_i|_{\gamma g_i F_i}$ is in M_i . $\square$

Lemma 3.11 (*About ψ_0*)

For all $\psi \in \Phi$, φ_ψ satisfies each property of Proposition 3.7 and that $|\varphi_\psi(w, v)| \leq \text{dist}(w, v)$, for all v and w .

Proof. Given a line l connecting v and w , we have $\varphi_\psi(v_{n+1}, v_n) \leq 1$ for every consecutive vertices v_n and v_{n+1} on l . Therefore, as φ_ψ is a global cocycle, $\varphi_\psi(v_m, v_n) \leq m - n$, which proves the claim. Properties 1 and 4 of Proposition 3.7 are satisfied because each element of our alphabet satisfy them in a cone. Property 2 (cocycle property) follows directly from the globalisation of φ_ψ by 3.9. For property 3, we notice that for γ_0 arbitrary, $\$$ can appear at most once in the set of values $\psi_i(\gamma_0\gamma)$ as γ ranges over G_i . If $[v, \xi)$ is a gradient line, with $v = \gamma_0 p_i$, for some i and some γ_0 , then, for γ such that $\psi_i(\gamma_0\gamma) = \$$, there exists γ' in F'_i such that $(\gamma_0\gamma\gamma').e_i$ is the first edge of $[v, \xi)$. If $[v, x]$ is a segment such that $\text{Ang}_v([v, x], [v, \xi)) \geq \theta$, then, for all $\gamma'' \in F'_i$, the edge $(\gamma_0\gamma\gamma'').e_i$ is not on $[v, x]$. Therefore, by the third property of the definition of the cylinder, $\varphi_\psi(x, v) \leq -\text{dist}(x, p_i)$. And this, together with $|\varphi_\psi(x, v)| \leq \text{dist}(x, v)$, gives $\varphi_\psi(x, v) = -\text{dist}(x, p_i)$. In other words, $[x, v] \cup [v, \xi)$ is a gradient line. $\square$

3.3 The presentation $\Pi : \Phi \rightarrow \partial\Gamma$

Given an element of Φ , we want to associate canonically an element of $\partial\Gamma$.

Definition 3.12 (Gradient lines)

Let ψ be an element of Φ . A gradient line l_ψ of ψ is a finite or infinite sequence $(v_n)_{n \geq 0}$ of vertices in $\mathcal{K}$ such that $\varphi_\psi(v_{n+1}, v_n) = 1$ for all n . Moreover, it is finite only if for the last index m , every neighbour v of v_m satisfies $\varphi_\psi(v, v_m) \leq 0$.

Lemma 3.13 *The gradient lines of the elements of Φ are geodesics in $\mathcal{K}$.*

Proof. First by 3.11 we have $|\varphi_\psi(w, v)| \leq \text{dist}(w, v)$, for all v and w . Now on a gradient line, we have by definition $\varphi_\psi(v_{n+1}, v_n) = 1$ for every consecutive vertices v_n and v_{n+1} on l_ψ . Therefore, as φ_ψ is a global cocycle, $\varphi_\psi(v_m, v_n) = m - n$. The triangular inequality gives the other inequality: $|\varphi_\psi(w, v)| \geq \text{dist}(w, v)$, and this proves the claim. $\square$

We now state and prove the main property of the elements of Φ .

Proposition 3.14 (Coherence of gradient lines)

Let $\psi \in \Phi$. All its gradient lines are asymptotic to each other. In other words they all converge to the same element of $\partial\mathcal{K} \cup \mathcal{V}_\infty$.

Before giving the proof of Proposition 3.14 we need some preliminary lemmas.

We say that two gradient lines of ψ are *divergent* if they are with different end points which are in the boundary or in the set of vertices of infinite valence.

Lemma 3.15 *Given two divergent gradient lines of ψ one can find two divergent gradient lines starting at the same vertex, or at two adjacent vertices.*

Proof. Let l_1 and l_2 be two divergent gradient lines, and v_1 and v_2 vertices on them. On a geodesic segment $[v_1, v_2]$, consider v the first vertex from which there is a gradient line l divergent from l_1 . Either $v = v_1$ (and we are in the first case of the lemma), or there is a vertex, v' , of $[v_1, v]$ adjacent to v . By definition of v , all gradient lines starting at v' are asymptotic to l_1 , and we are in the second case of the lemma. $\square$

Let l_1, l_2 and l_3 be three geodesic lines connecting respectively x_3, x_1 , x_3, x_2 and x_1, x_2 and suppose l_1 and l_2 are divergent gradient lines (possibly infinite) for ψ .

Lemma 3.16 *If v is a vertex of l_1 such that $(x_1 \cdot x_2)_{x_3} - 50\delta < \text{dist}(x_3, v) < (x_1 \cdot x_2)_{x_3} + 50\delta$ and if $\text{Ang}_v(l_1)$ is more than 5θ then the line l_2 pass through v and $\text{Ang}_v(l_1, l_2) \leq \theta$.*

Proof. It is enough to show that v is on l_2 , as we know by Lemma 3.11 that two gradient lines starting at the same point make an angle at this point smaller than θ .

At distance $(x_1 \cdot x_2)_{x_3} - 100\delta$ from x_3 , we connect l_1 and l_2 by a segment α_3 of length less than 10δ , and we connect l_1 to l_3 , and l_3 to l_2 at distance $(x_1 \cdot x_2)_{x_3} + 100\delta$ from x_3 by two others segments α_1, α_2 of length less than 10δ . In fact we will assume that such segments exist since that is the most complicated case, and otherwise one can reformulate the arguments in the next paragraph replacing the segments α_i by the vertices x_i in order to obtain the same result, namely v is either in l_2 or in l_3 .

Thus we have a loop of length less than 1000δ consisting of the 3 segments of length less than 10δ and the subsegments of each l_i lying in between the endpoints of these three segments. By Proposition 2.5, no circuit of this length contains an angle more than $1000\delta \leq \theta$. Hence, if v is a vertex of l_1 such that $(x_1 \cdot x_2)_{x_3} - 50\delta < \text{dist}(x_3, v) < (x_1 \cdot x_2)_{x_3} + 50\delta$ and if $\text{Ang}_v(l_1)$ is more than 5θ then either l_2 or l_3 pass through v as the segments connecting l_1 , l_2 and l_3 are 10δ short and 50δ far from v .

Now we assume that v is on l_3 and not on l_2 , and we now want to find a contradiction. In this case, we have a simple path from x_3 to x_2 consisting of the concatenation of the piece of l_1 between x_3 and v and the piece of l_3 between v and x_2 . The hyperbolicity of the space ensures that this path remains at distance less than 60δ from l_2 . We have now two possibilities, either l_2 goes at infinity or x_2 is in $\mathcal{V}_\infty$.

In first case we consider two adjacent vertices on l_2 , w and w' such that $\text{dist}(v, w) < \text{dist}(v, w') \leq 60\delta + 1$ (two such vertices necessarily exist since l_2 is a geodesic going to infinity). We choose a geodesic segment $[w', v]$ containing w . If $\text{Ang}_v([v, w'], [v, x_1]) < \theta$, then by triangular inequality for angles, $\text{Ang}_v([v, w'], [v, x_3]) \geq (5\theta - \theta)$, and therefore Lemma 2.6 for the triangle (x_3, v, w) implies that $v \in l_2$. On the other hand, if $\text{Ang}_v([v, w'], [v, x_1]) \geq \theta$, let us subdivide $[v, w']$ into maximal subsegments with maximal angle at most θ . Two consecutive such subsegments make an angle greater than θ . Lemma 3.11 (concerning the third point of Proposition 3.7) applied successively to each of these subsegments, proves that $[w', v]$ is a gradient line. This is a contradiction, since the edge (w, w') would be a gradient line in both directions.

In the second case there is no vertex w adjacent to x_2 with $\psi(w, x_2) = 1$. Now again if $\text{Ang}_v([v, x_2], [v, x_1]) < \theta$, then by triangular inequality for angles, $\text{Ang}_v([v, x_2], [v, x_3]) \geq (5\theta - \theta)$, and therefore Lemma 2.6 for the triangle (x_3, v, x_2) implies that $v \in l_2$. On the other hand, if $\text{Ang}_v([v, x_2], [v, x_1]) \geq \theta$, we subdivide $[v, x_2]$ into maximal subsegments with maximal angle at most θ and again by Lemma 3.11 applied successively to each of these subsegments, we prove that $[x_2, v]$ is a gradient line and hence the vertex w adjacent to x_2 in $[x_2, v]$ satisfies $\psi(w, x_2) = 1$, which is a contradiction.

This completes to proof of Lemma 3.16. $\square$

Proof of Prop. 3.14 . We argue by contradiction, and assume that l_1 and l_2 are two divergent gradient lines. Now by Lemma 3.15 we can assume that l_1 and l_2 are two divergent gradient lines starting at the same vertex, or at two adjacent vertices. In order to simplify the presentation we will only explicit the first case as the second case can be treated exactly with the same arguments. Thus we assume that l_1 and l_2 start at the same vertex, hence by Proposition 2.10, there is a geodesic (possibly bi-infinite) l_3 , such that (l_1, l_2, l_3) is a geodesic triangle with vertices x_1, x_2, x_3 (see Figure 1), with x_1 and x_2 possibly at infinity.

From the previous lemma, and the definition of the Gromov product, we see that a vertex in l_1 satisfying the assumption of the previous lemma is in fact located at distance less than $(x_1 \cdot x_2)_{x_3}$ from x_3 . Let v be the last vertex satisfying the assumptions of the previous lemma (or, if there is none, the vertex on l_1 at distance $(x_1 \cdot x_2)_{x_3} - 50\delta$ from x_3). The two rays do not

have an angle larger than 5θ after v , until they arrive at distance 50δ from the small segments connecting l_1, l_3 , and l_2, l_3 , because by the previous lemma, they would both pass by this vertex. Consider the cone centred on the first edge of l_1 after our vertex v , of angle and radius 10θ .

In this cone, let us parameterize the two subsegments of the two lines $l_i : [0, T_i] \rightarrow \text{Cone}_{10\theta, 10\theta}(v, e)$, for $i = 1, 2$. We know that $\text{dist}(l_1(0), l_2(0)) \leq \delta$, because the triangle (l_1, l_2, l_3) is δ -thin.

Moreover, as $\text{Ang}_v(l_1, l_2) \leq \theta$ (by 3.16) and as the two rays do not have angle larger than 5θ after v , until they arrive close to the transition segments, the vertices $l_1(T_1)$ and $l_2(T_2)$ are at distance at least $(x_1 \cdot x_2)_{x_3} + 20\delta$ from x_3 , and therefore, at distance at least 10δ from each other (see Figure 1), or possibly a segment l_i reach x_i , which, in this case, belong to the cone.

By definition of our alphabet $\mathcal{A}$, there must be a Busemann or a radial cocycle whose restriction on this cone gives rise to the same segments of gradient lines. This rules out the second case, and in the first case, by hyperbolicity, two geodesic rays with such subsegments would diverge at infinity, and we know that this cannot happen for gradient lines of Busemann or radial cocycles. This is a contradiction, and it proves the proposition. $\square$

Figure 1: Gradient lines and cone at the center of the triangle

We can now define the map $\Pi : \Phi \rightarrow \partial\Gamma$. For an element ψ in Φ , we associate $\Pi(\psi) \in \partial\Gamma$, the point to which any gradient line of φ_ψ converge.

3.4 End of the proof of Theorem 3.1

In order to complete the proof we need to show that $\Pi : \Phi \rightarrow \partial\Gamma$ satisfies the Definition 1.2 (Lemma 3.17), and secondly that the action of Γ on $\partial\mathcal{K}$ is expansive (Proposition 3.18).

Lemma 3.17 *The map $\Pi : \Phi \rightarrow \partial\Gamma$ is surjective continuous and equivariant.*

Proof. Given a point ξ in $\partial\Gamma$, by the visibility property, one can find a Busemann or a radial cocycle σ associated to ξ . We consider the function $\tilde{\sigma} : G \rightarrow \mathcal{A}'$ obtained by $\tilde{\sigma}(\gamma) = \sigma|_{\gamma \text{Cone}_{R, \Theta}(e_0, v_0)}$. Moreover, for every left coset γG_i , ($i = 1..m$), we fix a representant $\tilde{\gamma} G_i$. We consider the function, $\psi_i : G_i \rightarrow \mathcal{A}_i$, in Φ_i such that, if for some vertex v and $g \in G_i$ with $\tilde{\gamma} g e_i = (\tilde{\gamma} p_i, v)$ one has $\tilde{\sigma}(\gamma^{-1} v, p_i) < 0$ then ψ_i takes the value $\$$ at some such g .

For each i , the partition of Γ in G_i -left cosets defines a function $\tilde{\psi}_i : \Gamma \rightarrow \mathcal{A}_i$.

This gives an function $\varphi : \Gamma \rightarrow \mathcal{A}$, namely the product of $\tilde{\sigma}$ and of the $\tilde{\psi}_i$, $i = 1, \dots, m$ which is, by Proposition 3.7, an element of Φ whose gradient lines converge to ξ . Thus, the map is surjective.

If a sequence ψ_n of elements of Φ converges to ψ , then, given a finite set E of edges of $\mathcal{K}$, the gradient lines of ψ_n will coincide with the gradient lines of ψ on E for n sufficiently large. If the point at infinity ξ defined by ψ is in $\partial\mathcal{K}$, then by the usual topology of the boundary of $\mathcal{K}$, the sequence of points at infinity ξ_n , defined by the gradient lines of ψ_n , converges to ξ . If now

ξ is in $\mathcal{V}_\infty$, then, by convergence criterion given in paragraph 2.4, the sequence ξ_n converges to ξ . This ensures the continuity of Π .

Finally, if ψ is an element of Φ , and ρ one of its gradient line, then $\gamma\rho$ is a gradient line for $\gamma\psi$. The point at infinity of $\gamma\rho$ is by definition $\gamma\Pi(\psi)$, and it is therefore equal to $\Pi(\gamma\psi)$. Hence the map is equivariant. $\square$

Proposition 3.18 (*Expansivity*)

The action of a relatively hyperbolic group on its boundary is expansive.

Proof. If Δ is the diagonal of $(\partial\Gamma) \times (\partial\Gamma)$, then we have to find a neighborhood U of Δ such that $\Delta = \bigcap_{\gamma \in \Gamma} \gamma U$.

Let $\{e_1, \dots, e_m\}$ be a set of orbit representatives of the edges in $\mathcal{K}$. Let X be the set of pairs of points $(\xi_1, \xi_2) \in (\partial\mathcal{K})^2$ such that there is a bi-infinite geodesic between ξ_1 and ξ_2 passing through one of the e_i . Let now $\{p_1, \dots, p_l\}$ be a set of orbit representatives of the infinite valence points. Because they are bounded parabolic points, the stabilizer G_i of p_i acts on $\partial\Gamma \setminus \{p_i\}$ with compact quotient. Let then Y be the set of pairs of points (p_i, ζ) where ζ is in a chosen compact fundamental domain for the action of G_i .

We now choose $U = (\partial\Gamma \times \partial\Gamma) \setminus (X \cup Y)$. First we show that $\Delta = \bigcap_{\gamma \in \Gamma} \gamma U$. The direct inclusion is trivial.

Let $(\xi_1, \xi_2) \in U$ and assume it is not in Δ . We will show that it is not in every translate of U . We consider two cases, either ξ_1, ξ_2 are both in $\partial\mathcal{K}$, or one them, say ξ_1 , is a vertex of $\mathcal{K}$ of infinite valence. In the first case, there is a bi-infinite geodesic from one point to another, and it can be translated so that its image passes by one of the e_i . Therefore, there is γ such that $\gamma(\xi_1, \xi_2)$ is in X , hence not in U . In the second case, there is $\gamma \in \Gamma$ such that $\gamma\xi_1$ is one of the p_i . Now there is $\gamma' \in G_i$ such that $\gamma'\gamma(\xi_1, \xi_2)$ is in Y , hence not in U . This proves that the intersection of the translates of U is equal to the diagonal set.

Now we have to show that U is a neighborhood of Δ . That is to say that a sequence of elements in $X \cup Y$ cannot converge to a point of Δ .

Let $(x_n = (\xi_1^n, \xi_2^n))_n$ be a converging sequence of elements of X . After passing to a subsequence, one can assume that, for all n , there is a bi-infinite geodesic between ξ_1^n and ξ_2^n passing through a same edge e_i . If $\xi_1^n \rightarrow \zeta_1$ and $\xi_2^n \rightarrow \zeta_2$, we see that ζ_1 and ζ_2 are linked by a geodesic passing through e_i , hence non-trivial. Therefore $\zeta_1 \neq \zeta_2$.

Let now $(y_n = (\xi_1^n, \xi_2^n))_n$ be a converging sequence of elements of Y . After extraction, and without loss of generality, one can assume that $\xi_1^n = p_i$, for all n , and for some i . Then, ξ_2^n is in a compact fundamental domain for G_i in $\partial\Gamma \setminus \{p_i\}$, and therefore does not converge to p_i . This finally proves that U is a neighborhood of Δ , and ends the proof of Proposition 3.18. $\square$

4 Groups having the property of special symbol

In this section we give examples of groups with the property of special symbol, and we introduce a condition for it.

Let us begin with a necessary condition.

Proposition 4.1 *If Γ has the property of special symbol, then Γ is finitely generated.*

Proof. Let $\pi : \Phi \rightarrow \Gamma \cup \{\infty\}$ be a finite presentation with special symbol. Let $\mathcal{A}$ be the alphabet. Let $\mathcal{C}$ be a cylinder defining Φ , and itself defined by a non-empty finite subset F of Γ and a set, M , of maps from F to $\mathcal{A}$. The set of translates of F is a covering of Γ . Let P be the nerve of

the covering. As F is finite, P is a finite dimensional, locally finite complex on which Γ acts properly discontinuously cocompactly. The set of vertices of P is naturally identified with Γ . The claim is that P is connected. If it was not, there would be distinct connected components, C_i . Let γ_i be a vertex of C_i , and consider $\sigma_i \in \Phi$ such that $\pi(\sigma_i) = \gamma_i$. Let $\sigma \in \mathcal{A}^\Gamma$ such that $\sigma|_{C_i} \equiv \sigma_i|_{C_i}$. Now, σ has several special symbols (one in each C_i). On the other hand all the cylinder conditions defining Φ are satisfied, as by definition they are read on the connected components of P . This is a contradiction, and it proves the claim. Therefore, Γ is generated by F which is a finite set. $\square$

The next proposition is in fact is a slight variation of a theorem of Gromov, a detailed proof of which can be found in [5] (Corollary 8.2).

Proposition 4.2 *If Γ is a hyperbolic group, then it has the property of special symbol.*

Proof. We repeat the proof of the main theorem, seeing Γ relatively hyperbolic relative to the trivial subgroup $\{1\}$. A Cayley graph plays the role of $\mathcal{K}$, and we consider the same cocycles. They can define either a point at infinity, or a vertex of the graph. Thus, we obtain our presentation choosing the special symbol to be the restriction of a radial cocycle. $\square$

Although it could be seen as a consequence of the proposition above, the example 2 in part 1 already gave the basic examples of $\mathbb{Z}$ and of finite groups. Most of our remaining examples come from the following remarks.

Proposition 4.3 *If a group Γ splits in a short exact sequence $\{1\} \rightarrow N \rightarrow \Gamma \rightarrow H \rightarrow \{1\}$, and if both N and H have the property of special symbol, then Γ has the property of special symbol.*

Proposition 4.4 *Let G be a subgroup of finite index of a group Γ . The group G has the property of special symbol if, and only if, Γ has the property of special symbol.*

Before giving the proofs, we give a consequence. A group Γ is said to be *poly-hyperbolic* if there is a sequence of subgroups $\{1\} = N_0 \triangleleft N_1 \triangleleft \dots \triangleleft N_{k-1} \triangleleft N_k = \Gamma$, with all the quotients N_{i+1}/N_i hyperbolic.

Corollary 4.5 *Every poly-hyperbolic group has the property of special symbol. In particular, this includes virtually polycyclic (hence, also virtually nilpotent) groups.*

Proof. If Γ is poly-hyperbolic, there is a sequence of subgroups $\{1\} = N_0 \triangleleft N_1 \triangleleft \dots \triangleleft N_{k-1} \triangleleft N_k = \Gamma$, with all the quotients N_{i+1}/N_i hyperbolic. Using the Proposition 4.3, and the fact that hyperbolic groups have the property of special symbol, an induction on i tells that each N_i has the property of special symbol, and especially N_k which is Γ . $\square$

Proof of Prop. 4.3. Let us denote by $\mathcal{A}_N, \mathcal{A}_H, \mathcal{S}_N, \mathcal{S}_H, \mathcal{C}_N, \mathcal{C}_H, \Phi_N, \Phi_H$, the alphabets, special symbols, cylinders, and subshifts of finite type for the presentations of $N \cup \{\infty\}$ and $H \cup \{\infty\}$. Let F_N, F_H, M_N and M_H be the finite subsets of N and H , and the sets of maps defining the two given cylinders. From Proposition 4.1, N is finitely generated, then up to enlarging F_N , we can assume that F_N generates N (in fact, in the proof of Proposition 4.1, it is proved that necessarily, F_N generates N). Let $\mathcal{A} = \mathcal{A}_H \times \mathcal{A}_N$. Let us choose $\tilde{H}$ a set of representative of H in Γ , and for an element h in H , we write $\tilde{h}$ for the element of $\tilde{H}$ that maps on h by the quotient map. Let F be the finite subset of Γ defined by $F = \{\tilde{h}.n, h \in F_H, n \in F_N\}$. Let M be the following set of maps: $M = \{(m : F \rightarrow \mathcal{A}), \exists m_H \in M_H, \forall n \in F_N, m(\cdot.n)_1 = m_H ; \forall h \in F_H, m(\tilde{h}.\cdot)_2 \in M_N\}$, where the subscripts 1 and 2 denote the coordinates in the product $\mathcal{A} = \mathcal{A}_H \times \mathcal{A}_N$. Consider the cylinder defined by F and M , and the associated subshift of finite type, Φ . We need the following lemma.

Lemma 4.6 *For any $\sigma \in \Phi$, there is at most one element $\gamma \in \Gamma$ such that $\sigma(\gamma) = (\$H, \$N)$.*

Proof. We first prove that for any $\sigma \in \Phi$, there is at most one left coset of N , $\tilde{h}N$, such that $\forall n \in N$, $\sigma(\tilde{h}.n)_1 = \H . By definition of M , if $n \in F_N$, $n_0 \in N$, then $\sigma(\tilde{h}.n_0.n)_1$, the first coordinate of $\sigma(\tilde{h}.n_0.n)$ only depends on $\tilde{h}$ and n_0 . But F_N was chosen generating N , hence $\sigma(\tilde{h}.n_0.n)_1$ only depends on $\sigma(\tilde{h})$. But, by definition of M , the map $h \in H \mapsto \sigma(\tilde{h})_1$ is in Φ_H , and therefore, by the special symbol property, there is at most one value of $\tilde{h}$ where it takes the value $\$H$, this proves the first step of the lemma. Now, as the map from N to $\mathcal{A}_N$ defined by $(n \mapsto \sigma(\tilde{h}.n)_2)$ is in Φ_N , if $\tilde{h}$ is such that $\sigma(\tilde{h}.n)_1 = \H , there is at most one $n \in N$ such that $\sigma(\tilde{h}.n)_2 = \N . This proves the lemma. $\square$

Now, we define the map π so that it sends a element $\sigma \in \Phi$ on the point at infinity, if σ does not contain the symbol $(\$H, \$N)$, and on $\gamma \in \Gamma$ if $\sigma(\gamma) = (\$H, \$N)$. The map π is well defined, and gives a finite presentation with special symbol of $\Gamma \cup \{\infty\}$. $\square$

Proof of Prop. 4.4. Assume that Γ has the property of special symbol, and let $\mathcal{A}_\Gamma$, $\$_\Gamma$, $\mathcal{C}_\Gamma$, Φ_Γ the alphabet, special symbol, cylinder, and subshift of finite type associated. The cylinder is defined, as before, by two sets : $F_\Gamma \subset \Gamma$ and $M_\Gamma \subset \mathcal{A}^{F_\Gamma}$. We consider $\gamma_1, \dots, \gamma_n$ a set of orbit representatives of left coset of G in Γ , and we choose $F = (\bigcup_{i=1}^n \gamma_i^{-1} F_\Gamma) \cap G$, a finite subset of G . We set $\mathcal{A} = (\mathcal{A}_\Gamma)^n$ and $M \subset \mathcal{A}^F$ is the set of the maps m from F to $(\mathcal{A}_\Gamma)^n$ such that there exists $m_\Gamma \in M_\Gamma$ whose translates $\gamma_i^{-1} m_\Gamma$ coincide with the i -th coordinate of m . Those three choices define a subshift of finite type $\Phi \subset \mathcal{A}^G$. By definition of M , one sees that there is a natural map $\Phi \rightarrow \Phi_\Gamma$ which consists of defining $\sigma_\Gamma(\gamma)$ by the i th coordinate of $\sigma(\gamma_i^{-1} \gamma)$ if γ is in the coset $\gamma_i G$. This map is a bijection, its inverse being the map that associates to $\varphi \in \Phi_\Gamma$ the element $\sigma \in \Phi$ whose i -th coordinate coincide with $\gamma_i^{-1} \varphi$. Therefore, one has maps $\Phi \rightarrow \Gamma \cup \{\infty\} \rightarrow G \cup \{\infty\}$, the second map being identity on G and sending each γ_i to 1. At this point we do not have a special symbol, but, by property of Φ_Γ , an element of Φ can take a value in $\mathcal{A}$ which has $\$_\Gamma$ among its coordinates, only once. Hence, by renaming each of those symbol by a single one $\$$, we get the expected presentation with special symbol.

Conversely, it suffices to see that the intersection of all the conjugates of G is of finite index in Γ (hence it has the property of special symbol). It is normal and of finite index in Γ , and we can apply Proposition 4.3. $\square$
